Notes on Indian Astronomy

BY

DHIRENDRA NATH MOOKERJEE, B.Sc.

I

THE LIBRATION OF EQUINOXES

In the *Suryya Siddhanta* and other Hindu Astronomical works, we find the theory of the Libration of Equinoxes in which it is stated that the first point of Aries moves along the Ecliptic twenty-seven degrees on each side of the Nirayana Vindu, the fixed initial point. That is, in a certain number of years it goes twenty seven degrees away from the Initial point, then returns to it, again goes twenty-seven degrees the other side and comes back to the Initial point in a certain number of years.

The following extract from *Brennand's Hindu Astronomy* will show the universal acceptance of the theory of the Libration of Equinoxes and the Solstices by the Hindu astronomers. "This was a doctrine of a Libration of the Equinoctial and Solstitial points. Colebrooke in his essay on the equinoxes, has given the views of a number of writers on the subject; by some the motion is considered to be an entire revolution, through the whole of the asterisms; by others, and those the most numerous it was a libration, between certain limits on each side of a fixed point;..... In these two statements it may be noticed that Bhascara supposes the Equinoctial point is in motion, whereas the *Suryya Siddhanta* assumes that the entire circle of the Asterisms oscillates, first 27° on each

side of a mean point and then 27 degrees on the other side of that point. This supposed motion of the whole of the constellations may have led Bentley to assume that the ancient astronomers had two systems of Lunar Asterisms.....The theory of a libration, as expressed in various astronomical works, has been shown by Colebrooke to have been generally prevalent from very early times. It was also a doctrine maintained by Aryabhatta and Parasara, and by most of the Hindu astronomers of later times" (pp. 77-79). But this theory has been refuted by modern European astronomers' as will be seen from the following quotation from Lokmanya B. G. Tilak's *Orion*, page 82. "The hypothesis is now given up by modern astronomers as mathematically incorrect; but no reason has yet been assigned why it found place in the Hindu astronomy. A theory may be erroneous but even an erroneous theory cannot become prevalent without a good cause. It has been suggested by Bentley and approved by Prof. Whitney, that the limits of the libration might have been determined by the fact that the earliest recorded Hindu year had been made to begin when the sun entered the asterism of Krittika or $26^{\circ} 40'$ in front of Revati. But this alone is not enough to suggest the theory of libration. For, unless the Hindu astronomer had grounds—to him conclusive and otherwise inexplicable—for holding that the vernal equinox fell 27° on each side of Revati, he would not have proposed the libration of the equinoxes. So far as I know no such grounds have yet been discovered by modern scholars...." In this paper an attempt has been made to mathematically establish the conclusive grounds on which the Hindu astronomers based their theory of libration of Equinoxes.

* Colebrooke's translation of the *Surya Siddhanta*, pp. 244 to 249.

Now looking at the curve of the Equation of Time herewith appended, we find that the Equation of Time is influenced by two factors—the Obliquity of the Ecliptic and the Eccentricity. The curve for the Equation of Time due to the Obliquity and that due to the Eccentricity are drawn separately. Let us start for convenience from the time when the Aphelion coincided with the first point of Aries (which happened about 4000 B. C.)¹ and let us also assume that the Eccentricity and the Obliquity do not vary during one complete revolution. At this time the Equation of Time is zero at the vernal equinoctial point. As years pass on the aphelion goes ahead of the first point of Aries at the rate of 62 seconds ($50\cdot2''$ for precession and $11\cdot8''$ for the movement of the apsides) annually. Now looking at the curves we find that the maximum equation of time is $\pm 7\frac{1}{4}$ minutes due to the Eccentricity and this is attained about 90 degrees after the Perihelion or the Aphelion point (more correctly $88^{\circ} 50'$ after the Perihelion point). The corresponding degree in the curve for the obliquity at which the equation is $\pm 7\frac{1}{4}$ minutes is 27 degrees about, on either side of the Equinoctial or the Solstitial points.

This may also be seen from the following solution :—

The maximum Equation of Time due to Eccentricity being 7.68 minutes ($1^{\circ} 55'$) and that due to Obliquity being 9.9 minutes ($2^{\circ} 28'$), the mean Longitude of the point at which the Equation of Time is 7.68 min., on the curve for the Obliquity will be given by solving the following :

In a spherical right-angled triangle in which the hypotenuse is L, the mean longitude ($26^{\circ} 30'$), the angle adjacent is θ , the Obliquity of the ecliptic ($23^{\circ} 27'$)

¹ The earth being in aphelion on the vernal equinoctial day about 4000 B.C., graphically, first point of Aries and aphelion coincided then.

and the base is the R. A. (right ascension) to be found, we have

$$\begin{aligned}\tan R. A. &= \frac{R \cos \Omega}{\cot L}, \quad (R = \text{radius}). \\ &= \frac{R \cos 23^\circ 27'}{\cot 26^\circ 30'}\end{aligned}$$

$$R = 10.$$

$$\cos 23^\circ 27' = 9.9626$$

$$\cot 26^\circ 30' = 10.3023$$

$$\tan R. A. = 9.6603$$

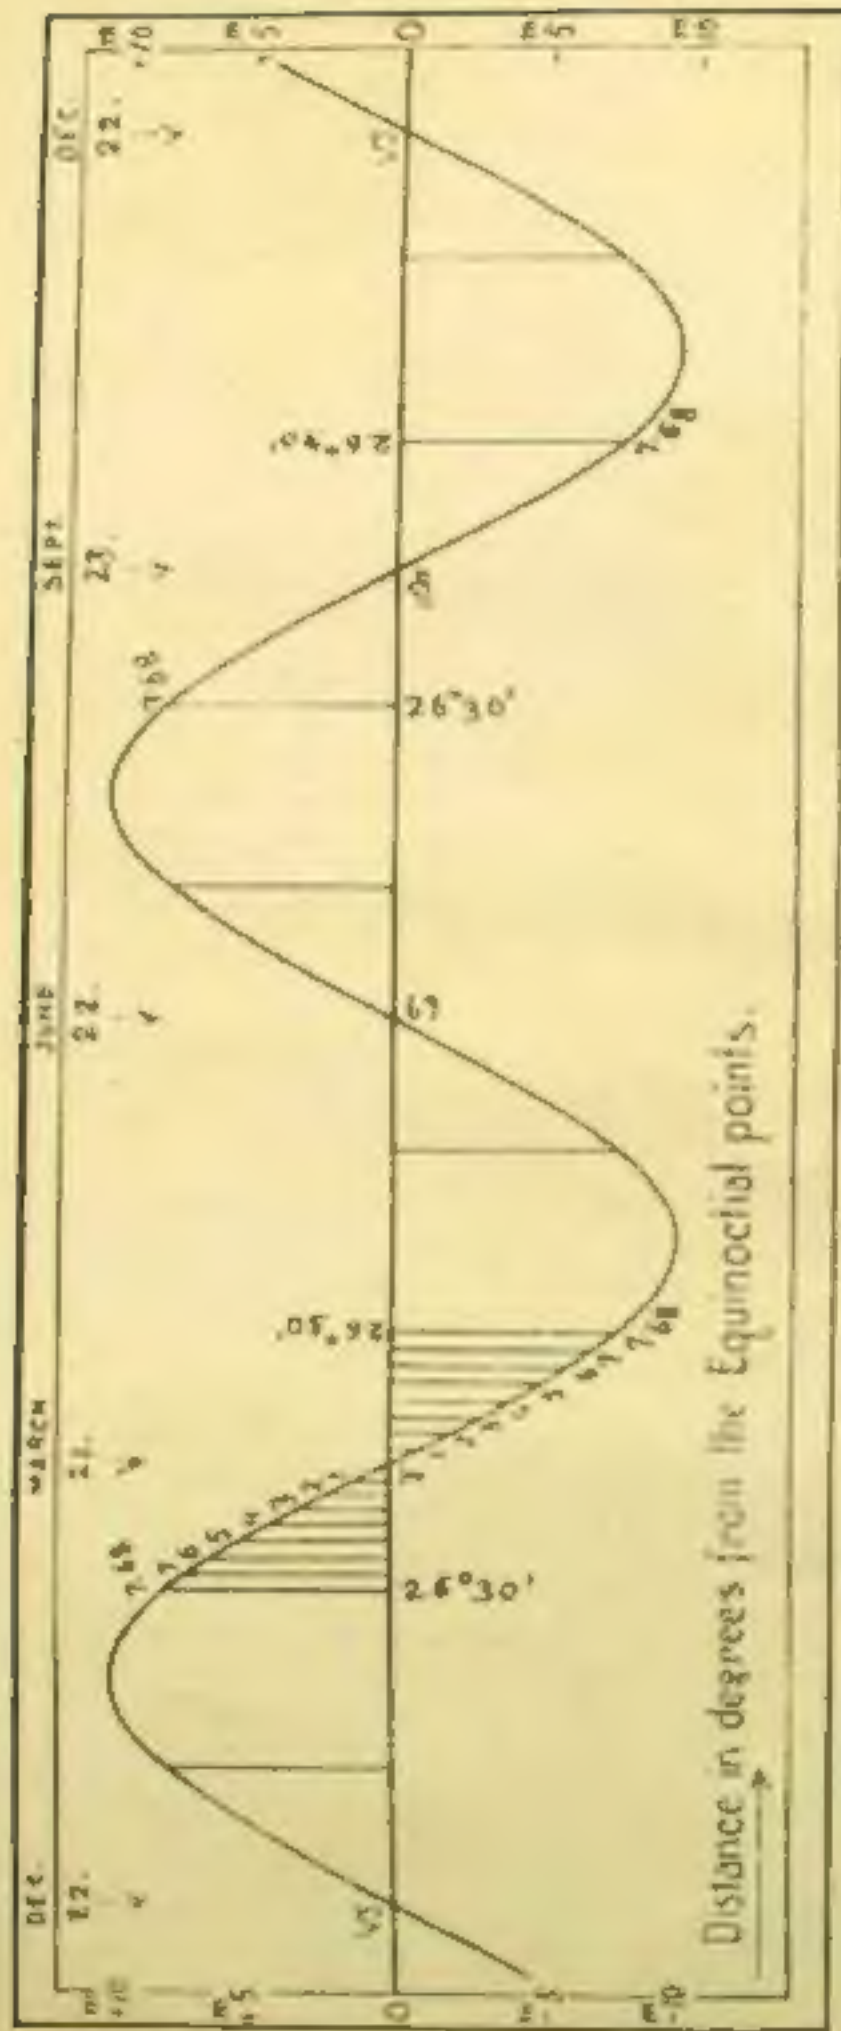

$$R. A. = 24^\circ 35'$$

\therefore Equation of time due to Obliquity $= L - R. A.$
 $= 26^\circ 30' - 24^\circ 35' = 1^\circ 55' (7.68 \text{ min.})$

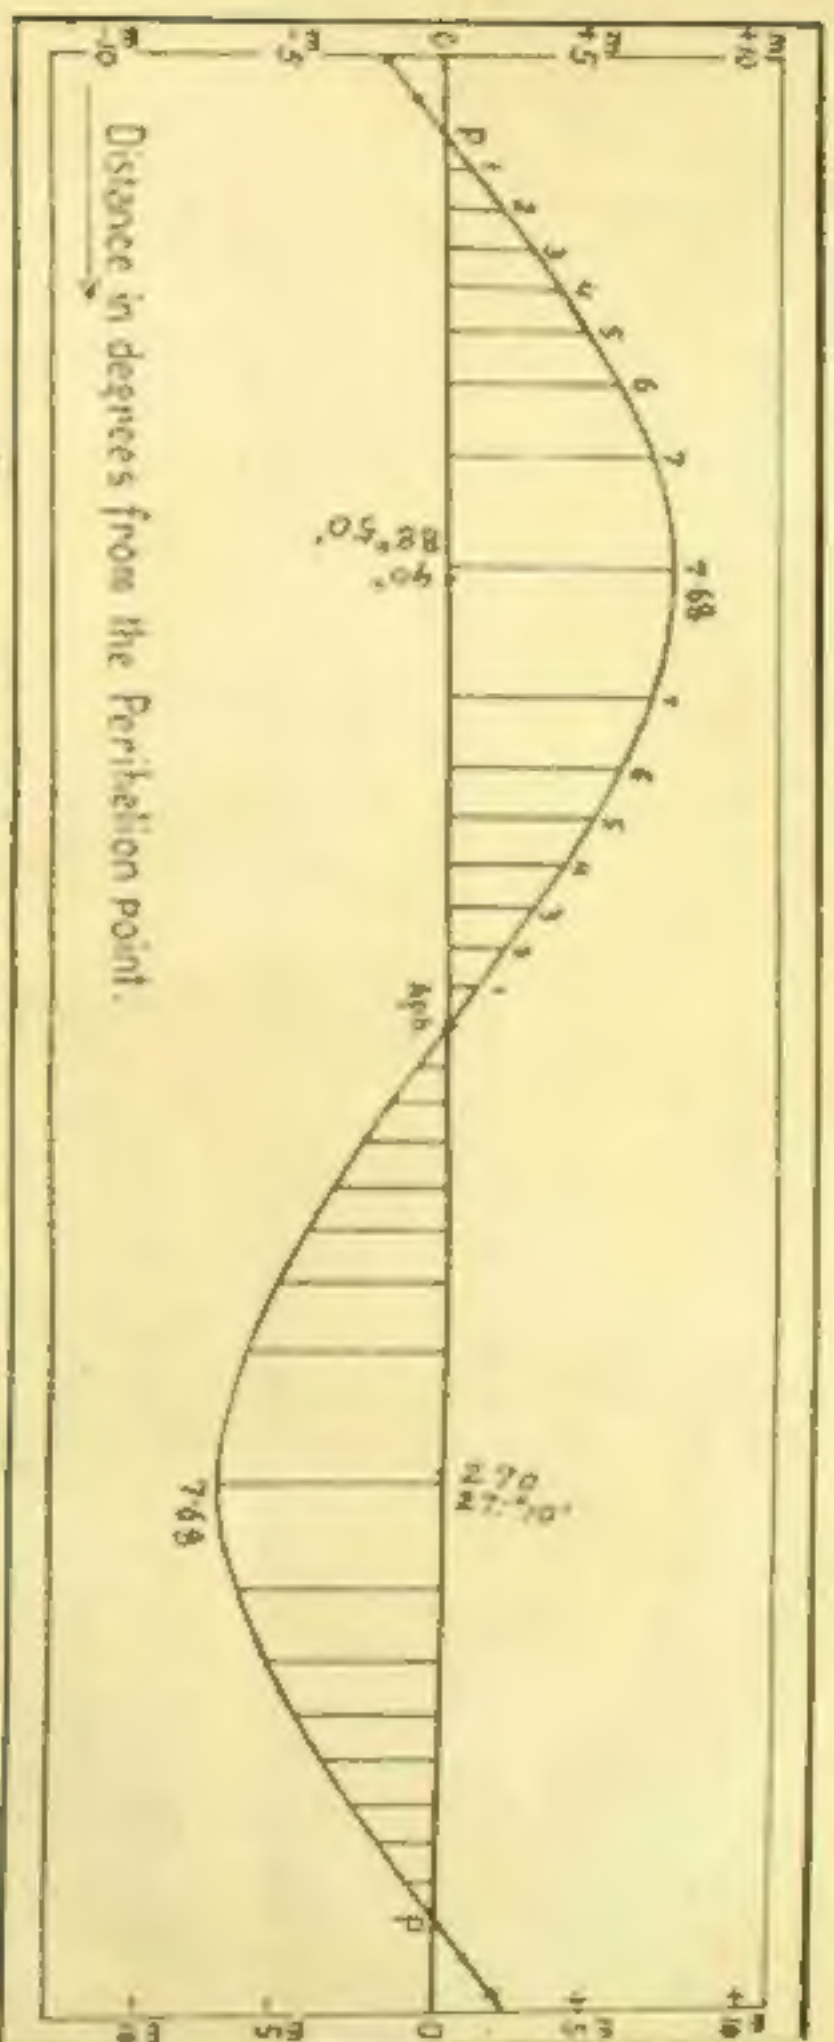

\therefore the mean longitude of the point at which the equation of time is 7.68 min. on the curve for the Obliquity is $26^\circ 30'$.

So the point near Aries at which the Equation of Time is zero oscillates about 27 degrees on either side of it.

Therefore when the Aphelion has advanced (90 plus 27) or 117 degrees from the first of Aries the longitude of the Sun on the day at which the Equation of Time is zero, is 27 degrees. This to occur, we have to shift the curve for the Eccentricity about 120 degrees keeping the curve for the Obliquity fixed. When the Aphelion will be advancing still further the Equation of Time will be zero—on dates earlier until the perihelion coincides with the first of Aries, at which time the Equation is zero at the vernal equinoctial day. This to take place the Eccentricity curve has to be shifted 60 degrees more. Let the aphelion advance 60 degrees further. The Equation is zero again at a point 27 degrees on the other side of the first of Aries after which time it is zero on earlier days and the aphelion advancing 120 degrees more coincides again with the first of Aries, when the equation is zero.

EQUATION OF TIME DUE TO OBLIQUITY OF ECLIPTIC.

Now assuming the point near Aries at which the Equation of Time is zero as the fixed Initial point it will be seen very clearly that the first point of Aries moves 27 degrees on one side or the other of this Initial point. This solution may similarly be extended to the other Equinoctial or the Solstitial points.¹

The periods of the above oscillations are the following :

1st period	(120 degrees movement)	$= \frac{120^\circ}{\frac{1}{60}} = 7200$ years.
2nd "	(60 " ")	$= \frac{60^\circ}{\frac{1}{60}} = 3600$ "
3rd "	(60 " ")	$= \frac{60^\circ}{\frac{1}{60}} = 3600$ "
4th "	(120 " ")	$= \frac{120^\circ}{\frac{1}{60}} = 7200$ "

Total 21600 years. Double this amount equals 43200 years. The reason for the adoption of the period of a Yuga as 432 and so many zeros is now apparent. The oscillatory period of 108 degrees is 21600 years (about 20 86 according to modern European Astronomy). Therefore in a Yuga of 4320000 years there are 200 complete revolutions. The period of 21600 years may be divided into three periods of 7200, 7200 and 7200 (3600 plus 3600) years. Each of these periods is the 600th part of a Yuga.

¹ The maximum Libration of Solstices is 24° 30'. This explains Aryabhatta's 24° of the Libration of Solstices (Ayanas) as 24 degrees.

This is the reason why Ranganath the great astronomer commentator of the *Suryya Siddhanta* mentions this revolution as *bilakakana*, possessed of peculiar characteristics.

It is clear, the Hindus carried their observation assiduously at least from 12000 B.C. to about 3500 B.C. to expound the Libration of Equinoxes in which case the Hindu civilization is at least 14000 years old.

Now to find the Ayanamsa. When the R.A. of the Sun is 120 degrees his longitude is about 117 degrees. When the distance between the Nirayana Vindu and aphelion is 90 degrees, the distance between the first of Aries and the Nirayana point is 27 degrees; this is the Ayanamsa then. In other words the difference between the longitude of the sun on the day on which the equation is zero nearest the vernal Equinox, and that of the vernal Equinox is the Ayanamsa for a particular year. Taking the case of the present time the difference between the longitude of the sun on the 14th of April and when the earth is in aphelion on July 2nd (which is the *bhujā*), about 77 degrees, the Ayanamsa should be $\frac{77 \times 27}{90} = 23$ degrees about. This is the same as the longitude of the Sun on the 14th of April at which date the equation is zero.

We also observe that when the mean time is less than the apparent time on the vernal equinoctial day, the first point of Aries is to be looked for to the east of the Initial point (the point nearest Aries at which equation of time is zero). This was the case from about 13000 to 4000 B.C. When mean time is greater than the apparent on the vernal equinoctial day, the first point of Aries is towards the west of the Initial point, as it is at present. This is what verse 11 and 12—Chap. III, *Suryya Siddhanta*—really mean.

This is in brief the explanation of the Libration of Equinoxes as expounded by the ancient Hindu

Astronomy is the Hindu Science which is neither adopted nor dropped. It is always there, altogether. This is not to be taken as one of the strongest arguments of the independent origin of Indian Astronomy.

Taking the first day of the Hindu Nirayana year to indicate the day when the Equation of Time is zero nearest the Vernal Equinox (about April 14th now) it is clear the Vernal Equinox must happen earlier or later by 27 days, in a cycle of about 21000 years.

If now the study of Hindu Astronomy and chronological events be conducted in the light of the above explanation, I am confident all anomalies and discrepancies will disappear to the great satisfaction of all students.

With great pleasure being a young student of astronomy I place these few lines before the mathematicians and astronomers with the hope that they will examine the above statements and see if the Equation Theory of the Hindus has been correctly solved.

In conclusion I acknowledge my indebtedness to Anantash Mitter Esq. Professor, Vidyasagar College, from whom I got valuable help in various matters and had portions of the Surya Siddhanta letter where I got this explanation might not have struck my imagination.

Addendum (to paper on Equation of Equinoxes)

Burgess has translated the Surya Siddhanta Journal of the American Oriental Society Vol. VII pages 244 to 249, discussing the theory of Equation of Equinoxes expounded by the ancient Hindu Astronomers. Here I quote a few lines from his remarks.

Now it is not a little difficult to suppose that a phenomenon of so much consequence as this which enters as an element into so many astronomical processes

should have been hidden away thus in a pair of verses
p. 246

Bhaskara's considerations drawn from the general history of Hindu astronomy and the position of the element of the precession in the Surya Siddhanta we have seen to be the blind and incoherent, as well as unusual form of statement of the phenomenon, as fully exposed above. . . . " p. 247

" Bhaskara's own commentators . . . hold to that of a libration which has been and is together the prevailing doctrine through all India and seems to have made its way thence into the Arabian and even into the early European astronomy (see Cockburne as above). What Bhaskara mentions in his *Siddhanta* *Shunya* (*Goladya Goladanthadikaryasikha* 17 and 18) as 'Avanti Chakram' movement of the first point of Aries or Libra and the period of revolution is clear from his own notes on the same. 'This is nothing but the movement of a fixed equinox with reference to the aphelion. The period of a complete revolution of the perihelion or the aphelion with reference to a fixed equinox is according to modern astronomy 20984 years (annual movement 610 seconds). This according to Bhaskara is 21636 years (annual movement 590 seconds). This is the same as the period of one complete libratory movement.

Now I shall make it clear that the Greeks also adopted the same sort of year calculation as the Hindus. Young in his "Manual of Astronomy," page 114, says, "He (Hipparchus) found that the year of the seasons, from solstice to solstice, as determined by the Gnomon, was shorter than that determined by the helical rising and setting of the stars (i.e., the times when certain constellations rise and set with the sun), just as if the Equinox preceded i.e. 'stepped forward' a little to meet the sun." Regarding the amount of precession determined by

Hipparchus *Recherches* 1858. Among the Greek astronomers Hipparchus is credited as the first who discovered the precession of the equinoxes, their exact motion however, seems not to have been correctly determined by him, although he pretends it to be at any rate not less than $36''$ yearly.*

Ptolemy however was so indolent as to adopt for the true rate Hipparchus' number of $36''$ a year. (p. 249). Now in the explanation of the Libration of Equinoxes I have shown that in about 7200 years from B.C. 1000 and onwards the maximum libration of about $27''$ will be attained (please see the last diagram in the paper). Now assuming the Sun's daily motion to be $1'$, we see that in 7200 tropical years and 27 days, 7200 Niryam years are completed. Therefore one Niryam year is $\frac{1}{7200}$ day or 0.00475 day longer (under the present conditions) than the tropical year. Therefore the present Niryam year is equal to $(365.24219 + 0.00475)$ days or 365.24694 days. The difference between the Sidereal and tropical year being 0.01417 day during this time 504 seconds of arc of the ecliptic are passed over. The difference between the Niryam year (for the present) and the Sidereal year being 0.01042 d., the number of seconds of arc passed over during this time is got by simple proportion

$$0.01417 \text{ d.} : 0.01042 \text{ d.} :: 50.4'' : x''$$

$$\therefore x = \frac{0.01042 \times 50.4}{0.01417} \text{ or } 36.8'',$$

This is the amount of precession determined by Hipparchus and Ptolemy. Therefore they certainly used this year which began on the day when the mean time and Sun dial time were the same nearest the Vernal Equinox. This to be true the length of the year calculated by Hipparchus and Ptolemy ought to be about 0.00475 d. or 5.34 minutes longer than the tropical

NOTES ON INDIAN ASTRONOMY

lines from San'yth's 'Cave' will be read with keen interest by all. 'Tribh' (Tribhukorah) was also a clever astronomer and is said to have improved what Forghat prepared. He however is particularly remarkable for having revived the old notion of a variation in the position of the ecliptic as well as in the fixed stars, which has been called the trepidation. It was his opinion founded on some erroneous observations, that the stars moved for some time according to the order of the signs, that they afterwards proceeded in a retrograde direction, and returned to their former places after which they assumed a direct motion, and that they even had an irregular motion which was rapid for a certain period then became slower and at last insensible. He maintained that the obliquity of the ecliptic was variable under similar periods of increase and decrease, and calculations provided for a considerable time (p. 28). A glance at the figure in page 281 will explain the above sentiments regarding trepidation or Libration of Equinoxes. Therefore now the explanation of the theory of the Libration of Equinoxes will be sent to us.

II

THE LIBRATION OF COLURES AND CONSEQUENT
CHANGES IN THE COMMENCEMENT OF THE HINDU
NIRAYANA YEAR

In my previous article I endeavoured to interpret in the correct way the theory of Libration of Equinoxes now universally accepted by the Hindu astronomers. The Libration theory being accepted the next problem which presents itself, is, how to keep the correlation between the fixed asterisms (stars) and Nakshatras and the months of the year (as prescribed by the Hindu astronomers), unchanged, when both the first point of Aries and the point nearest it where the equation of time is zero, are not fixed with respect to the stars. From the following considerations it will be seen how this problem had been solved in the past by the Hindu astronomers and how it has to be tackled in future.

The point in the Ecliptic nearest the Vernal Equinox at which the Equation of Time is zero, marks the starting point for the commencement of the Hindu Nirayana year (Nirayana Samvat). Now and again (on parting of the mean and apparent Suns about the Vernal Equinoctial point) when this point recedes 70 degrees from a point in the Ecliptic which is recognised as the beginning of one of the twelve constellations of the zodiac (the fixed Stars), a change is introduced in the beginning of the year, namely one extra sidereal month is added to keep the relation between the fixed asterisms and the names of the months intact. In so doing the precessional period (the period of the recession of the equinox) has to be

taken into account, it will be seen that the following example:

Assuming the Vernal Equinox and the Equation of Time zero coincident in 1000 B.C. at 70 degrees Longitude (Hindu data), they were again coincident 10800 years before the time. During this time Vernal Equinox occurred 10800 \times 18 seconds = 144 hours or a Longitude $273 = 70$ plus 144 or the Equation of Time was zero and the Vernal Equinox was coincident. On modern data this happened when the Vernal Equinox was happening at about 120 Longitude.

Brahmagupta's Hindu astronomy 4 page 77 says "For the theory of the revolution of the spheres there was a rival doctrine." This was the doctrine of the Equation of the Equation of Time and the Seasons periods. There are however no rival doctrines but Hindus going hand in hand with the Hindu astronomers. The period of the revolution of spheres is 10,800 and 27,000 years according to the Hindu astronomers. 2,868 years a modern astronomer. If we assume the year to be divided into equal periods each with a precession of time of 1000 years we get 24 such periods or representation 14, 20. This is the origin of the Hindu system of the twenty-seven Nakshatras (constellations) and Abhrit (alpha Lyræ) was the brightest star in the northern hemisphere occupying the position of the star of the Pole Star at the present period when the constellation of Agrahayan was the first one in the year. Adept from prefix 'abhi' and 'rit' अभि रित to disappear. Abhrit became the pole star and thus being the center of the world he or she began to be crowned Abhrit as the deity of the world. When Abhrit was no longer the pole star naturally it was left out of the reckoning.

The table appended herewith has been constructed to show the probable periods of the successive year

beginnings, the names and dates of the months beginning the year for the periods etc., etc. This is computed according to an old Indian chronological data starting from Agrahayana as the first month of the year. The difference between the two sets of results is not much owing to the fact that the dates between the two sets of data are about the same.

$$\frac{27000}{21600} = 1.25; \text{ also } \frac{25968}{20946} = 1.24$$

On looking at the table for the period beginning with the month of Agrahayana we notice that the year began when the sun was exactly in the beginning of the asterism Mithra. The Vernal Equinoctial circle passed through Jyestha, Antares and Abhaya (Arcturus), the star Abhaya (Vega) was also the pole star of the period. The autumnal Equinox passed through Rohini, Aldebaran, and six months after the first of Agrahayana we have the Orion group (Mergis etc.). The solstitial circle passed through Purva Phalguni, delta Leonis, and Sathabhis (Aquarius). Now the meaning of the month as Mergis etc. and the significance of 1 on Mergis etc. of the months and Abhaya of the Nakshatras of the Bhargava is now clear. The name of the summer of Nakshatra Mithra (the root), Jyestha (the first) and of Rohini (from *rodhan* or

abakobor, ascent or descent of the Sun from the Equator, according as the observer is situated to the north or the south of it, will now be understood.

Next coming to the year when the year began with the month of Kachik we meet with the peculiar phenomenon that here too Equinox of Time was zero at the Vernal Equinox (the point where 22° the longitude of $100^{\circ} 20'$ here). According to Hindu data when the Vernal Equinox was at 13° the Equinox of Time was zero exactly at that point, because the star *Abhaya* (Baskin) exactly on the Equator. Pictorially *Abhaya* represents the position of $10^{\circ} 44'$ the two arms of the balance. Thus a balancing of the two things have occurred in the balancing of the period and the origin of the name of the Nakshatra Baskin from *abakobor* the two arms of the balance and that of the Rasi Tula (Libra) from *abakobor* from *abakobor* indicating opposite will now be evident. A similar junction of the two phenomena occurred at 8° long modern data, or 7° long Hindu data and here is the beginning of the Rasi Mithuna (Gemini) and thus the origin of the name of the Rasi Mithuna is clear.

Now when the point at which the Equinox of Time is zero, i.e. at the Vernal Equinox will coincide with the longitude of the star Revati, a change has to be introduced. The exact year at which this will happen has to be determined by practical astronomers. In a congress of the Indian astronomers it has to be declared that that particular year will have two Phalguna months and thereforwards the 1st of Chaitra will be the first day of the succeeding years and another change has to be effected which will not take place before about 1800 years after that. For this change the Hindus will not have any objection seeing their ancestors have done the same several times. (cf. *Index Orion*, pp. 198-200)

At the commencement of the period beginning with the month of Baisakh, Vernal Equinox fell at 36 degrees and the Equation of Time was zero, the asterism of KRITIKA. At this time the Nakshatra Kratika was the first of the series :—

देवशृङ्गायै नमस्तानि । कुलिका प्रथम । विशाखे वृत्तम् । तानि
देव नमस्तानि । तन्निगद्य ब्रह्मण ।

But during Varaha Mihira's time Vernal Equinox was happening in Revati so the Equation of Time was zero, that is, the year began, in Aswini (alpha Aries). This being so Varaha Mihira and others were bound to put the Aswini system in place of the Kratika. It was on the moon we are relying, as inferred by the astronomer, every three years and we shall have to do the same in the case of the sun, allowing him two intercalary solar month at the end of, say, 2000 or 3000 years to keep his relation with the Rasis and Nakshatras intact.

Here I have tried only to give a general survey of the Hindu system of year beginnings consistent with and consequent on the theory of the Libration of Equinoxes which should no longer be considered as a mere matter of speculation in which the Hindus revelled, but as astronomical truth which they discovered after assiduous observations extending over thousands of years.

III

THE SO-CALLED SIDEREAL YEAR AND THE SIDEREAL PERIODS OF THE PLANETS IN HINDI ASTRONOMY.

The term *Saura Varsha* *Sauravarsha* is met with in all dated astronomical works. This is translated as the *Solar Year* because it is the year reckoned by the *Surya Siddhanta* and other Hindu Astronomical works. Now why should the *Saura Sauravarsha* be understood as the *Solar year* if it is not to be understood? Burgess in his translation of the *Surya Siddhanta* page 400—*minutes*—“The *Saur Year* is directly noticed as sidereal and tropical—the length of the solar year and month is subject only to a retrograde variation due to the slow motion of the apsides in 57 years—assumed for the Sun’s line of apses.” Now the question is if the Hindu *Saur Year* is sidereal, how can the length of it vary at all even for a few years? The length of years I have never heard of varying in any sense, and the sidereal year is a fixed measure of the revolution of the Sun’s line of apses. It is to be noted that Burgess has estimated upon an error. I can well understand the essential quality of a student’s work, but it is quite incompatible. Instead of assuming that we might assume that the motion of the apses is only $0.1161''$ seconds per minute it was supposed that it was nothing but the *Sidereal Year*, the difference being 24 hours or 86400 seconds. The period of the planets is given for about the centre of the apse, which is the true, which it takes the latter to make the difference of the orbit from the apsis

from 1 to 12, and is not a constant, but varies with the star revolution. This is most properly applied to the period of sidereal revolution of the moon, and it is not surprising that the moon's sidereal period is not exactly the Hindu year as stated by Bhaṣkara, *Trisandhan*, p. 88, page 307. But the right value should have been given to put it that the Hindu Solar Year is 365.2586 days, and to say that with the Hindu astronomers the difference between the sidereal and the solar years is 1000 seconds. Then it would have been easy for me to find the number of the Sun's true revolutions is equal to given by the Sidhartha. The fact is that the annual motion of the equinox should be 441 seconds or 7.4 minutes seconds. The number of revolutions of the Sun's apses in a Kṛpā's year in the S.S. = Sun's sidhartha is 487. This is certainly the number of revolutions of 4.2×10^4 years. The number of revolutions calculated from modern astronomy is 494. The rotations in a Kṛpā of 432×10^4 years should be 4870. The sidhartha is most of the time of apses in modern astronomy is 11.79 seconds. Goddard has it 11.76. Consequently the sidhartha year is 365.2586 days. The 2.9 Sidhartha is 1365. The Hindu solar year is about 365.2586 days. The 4870 days, the difference being only 30 minutes and 50 seconds. This year was certainly not made by the Hindu astronomers to be used in the year of sidhartha and civil reckoning. That year was of the Sidhartha. No year was to accomplish an epoch it started from a epoch in which the Kṛpā's apses and the true year when it started the beginning of the true sidhartha started. It was then observed that the sidhartha year is equal of these phenomena epoch. As an example let us assume the Aequinox and perihelion epoch after 24000 years the Aequinox and the perihelion star coincide after 24000 years. Therefore after five

conjunctions of the Equinox and the apses 5×21000 years or 105000 years, or four conjunctions of the Equinox and the star 4×27000 years or 108000 years, the Equinox, apses and the particular star coincide. The period in which mankind in general are interested is the tropical year, or when the return of the seasons depends. But in this tropical year we are not so taken of the position of the apses on which the severity or mildness of the seasons depends. The Hindu New Year is the result of the period of the movement of the Equinox and the apses (please see my first article on 'Labitation of Equinoxes' and as such it is the period in which mankind in general are most interested. Now we are perched on being a January and aphelion in July we northerners are having short less severe winter and long mild summer. But after ten thousand years from now when aphelion will be in January and perihelion in July the extremes summer and winter of these northern lands here will be transferred to us. Therefore the character of our New Year by the Hindus is more natural and scientific than the tropical. The period of the Solar Year (sidereal) was mentioned in the Siddhantis as it would be of much help to the astronomers for their calculations.

Now I shall pass on to the so-called sidereal periods of the planets Mercury, Venus, Mars, Jupiter and Saturn as found in Hindu astronomical works. The period of Mars is given in the S. S. as 68699749 mean solar days. The sidereal period is evidently 6869797 days. The mean annual movement of the apses of Mars is 1.82 seconds. Therefore the apses of Mars has advanced 1.82×1.88 (sidereal period of Mars in years) seconds in one sidereal revolution. On calculation the sidereal period of Mars comes out to be 6869797.02 days.

The period of Saturn as given in the S. S. is 10765.77

days. The sidereal period of Saturn in modern astronomy is 10759.22 days, a difference not to be easily passed over. Now the mean annual movement of Saturn's apses is 19.37 seconds. Therefore the apses of Saturn has moved in one sidereal revolution 19.37×29.46 period of Saturn in years seconds or 57064 seconds. The mean daily motion of Saturn being 120.5 seconds it will take $(57064 \div 120.5) = 474$ days more for Saturn to reach the perihelion. Therefore the anomalistic period of Saturn comes out to be 10764.96 days. But it is worth while noticing that the period as corrected by the *Ripa* is 10764.89 days. Similarly the sidereal period of Mercury being 87.9693 days, the anomalistic period is 87.9694 days (assuming the mean annual movement of the apses to be 5.84 seconds). The period in the *Surya Siddhanta* is 87.9697 days. The sidereal period of Venus being 224.7008 days, and the mean annual movement of her apses being 2.68 seconds towards the west, one would naturally expect the period as given in the *Siddhantas* to be shorter than the sidereal period (supposing the Hindu periods anomalistic), and strange enough the period in the *Surya Siddhanta* is 224.6486 days, that corrected by the *Tipa* is 224.6900 mean solar days (the anomalistic period calculated on modern data is 224.7005), both shorter than the sidereal period. The sidereal period of Jupiter being 4332.58 days, the anomalistic period should be 4332.85 days (assuming the mean annual movement of the apses to be 6.65 seconds). The period in the *Surya Siddhanta* is 4332.32 days. This even after correction by the *Tipa* is 4332.42 days, shorter than the sidereal period.

This shortening of the period of Jupiter and the lengthening of that of Saturn are due to this. * The remarkable fact, however that the mean motion of Jupiter was then more rapid and that of Saturn less so than it had formerly been was detected. This

anomalous phenomenon, which is now so well known to be caused by the mutual perturbations of those planets on each other, was a startling difficulty, but Cassini investigated the conditions, and boldly conjectured that the time would arrive, when those effects would be of a contrary nature. His happy prediction has been beautifully verified. — Smyth's 'Cycle' p. 52.

Now one may ask, assuming these periods in the Siddhantas to be anomalistic, what about the period of the moon which is exactly sidereal? The answer to this is that the position of the full-moon among the well known twenty-seven asterisms of the Hindus gives rise to the names of the months and this is happening since time immemorial, and as such astronomers are bound to give prominence to her sidereal period. "Naturally enough since the moon is the most conspicuous of the nightly luminaries, and her revolutions more rapid and far more important than those of the others, the asterisms would practically be brought into much more frequent use in connexion with her movements." — Burgess Translation of the *Surya Siddhanta*, page 352. The anomalistic and draconitic (nodical) periods may be easily calculated from the data given in the Siddhantas.

Here I add a table of the revolutions and movements of the apsides and nodes of the Planets according to the *Surya Siddhanta* and modern data. The revolutions are for the period 432×10^3 years, assuming the values as given in Watson's *Theoretical Astronomy* and in Smyth's *Cycle of Celestial Objects* to remain constant through ages. The revolutions according to the *Surya Siddhanta* are certainly for the same period (432×10^3 years). The design in putting the revolutions of the Planets in 432×10^3 years is that we can find the movement in a century in seconds by simply multiplying by 3. Thus the revolution of the Sun's apsis in 432×10^3 years being 387,

Planets	Revolutions in 432×10^4 years.	Movement in a Century.
	(Modern.) (S. S.)	(Modern.) (S. S.)
Mars apogee node	527 776 204	612 642 782
Mercury apogee node	106 264 688	1164 1664 2760
Jupiter apogee node	222 527 930	2760 527 930
Venus apogee node	58 624 901	1871 2760 3760
Saturn apogee node	646 647 20	1077 1042 117
Sun apogee	303	1170
Moon apogee node	488230 332230	401" (daily) 130" (daily)
		1654000" (daily) 6867147" (daily)

* Should the gifted astronomer of Canino, by inserting in an observation made B. C. 300, and comparing this with the position during his time, calculated that in 1534 years Jupiter's node have retrograded with respect to the fixed stars, as much as 141 degrees. This gives the movement in a century as 2760 arcseconds.

the movement in a century is (387×3) or $1161''$ seconds. Hence the annual movement is $11.61''$ seconds. In some cases it will be seen that the values are almost the same with modern mean values, in others certainly errors have crept in. A glance at the table will show that the values for Mars and Mercury had been interchanged. From the manner of writing the two words Kuja, कुज Budha बुध or Kauja (कौज) and Baudha (बौध) in Devanagiri type this error has crept in. The same error will be observed about Mars and Mercury while speaking of the retrogradations of the Planets in verses 53 and 54, chapter II, Suryya Siddhanta. In support of this as to how errors have crept in and accumulated, I shall quote here what that great genius Bhaskaracharyya said in connection with this very subject in his Siddhanta-Sirumani :

“या तु गतं मास-कुशलं ततः विषमं कालं पुनरीतिर एव वीतुं शक्यते न अन्यथा ।
 एतन्मते ग्रीष्मं याताः सः सः मासं वक्ष्यन् एतावत् पश्यन् कल्पं कुर्वन्ति इति अतः आरम्भ एव

३

एतन्मते मासमाधिकारि भवत्यानाम् ।

Now some may doubt that as the revolution is said to be completed when the Planet returns to Revati, how can these be the anomalistic periods? I wish them to ponder over the original text : “.....पौष्णाम्ने भवणः क्षुरः ।”

पौष्ण from पृथ्वी (the sun)¹ चन्ते निकटे (पौष्णस्य रेवती योग-
 ताराया चन्ते निकटे प्रदेशे, etc., Ranganath), whether it does
 not mean the perihelion and consequently the anomalistic
 period. The secondary meaning is the star Revati with
 which the apsis was coincident in the beginning.
 Similarly 'Meshadi' (first of Aries) or end of Revati came
 to mean the Initial or starting point—the first point of
 Aries in the case of tropical revolution the aphelion point
 in the case of anomalistic revolution, etc. *Fide Suryya*
Siddhanta verses 45, 48, 57 and 67, Chap. XII, and
 Ranganath's commentary on verse 48. "मेघादौ विपुलं
 वृत्तस्य क्रान्तिवृत्तभागे रेवत्यासुखे, etc." Moreover the mention
 of Revati 'Tara' does not mean that we are to look
 always for a particular star shining in the heavens just
 as we are not to understand the expression 'Dhruva Tara'
 as the two pole stars shining through ages in the heavens,
 but simply 'as the poles: 'ध्रुवयोर्दक्षिणोत्तरस्थिरतारयो वरु-
 णक्षणाभिवर्द्ध, etc.'—Ranganath, notes on sloka 73, Chap. XII,
 also verse 43 of the same chapter मेरोदभयतो मध्ये ध्रुवतारे
 नभःस्थिते । निरक्ष देशे संख्यन्त्यमुभयं क्षितिजायये ॥ "In both
 direction from Meru are two pole-stars, fixed in the midst
 of the sky: to those who are situated in place of no
 latitude, both these have their places in the horizon"
 Regarding 'Bhagana'—हादगराग्निभोगाद् भगण इत्ययः—Ranga-
 nath, note on verse 27, Chap. I. These rasis may be
 Sayana, Nirayana, etc.—"हादगराग्निकृते वृत्ते उच्यमानात्
 चतुर्विभागान्मक एकेको भागो रागिचयात्कोपदसंज्ञः—Ranganath,
 Chap. II. 29. *Fide* also "अज्ञादि केन्द्रे सर्वेषां गौणे मान्दे च
 कर्मणि । अत्र यद्वाणां लिप्तादितुलादाह्वयमेव च ॥—Chap. II. 45.
 "There is nowhere in this work any allusion to them
 (Hindu names of the signs) as constellation, or as having
 any fixed position of their own in the heavens: they are
 simply the names of the successive signs (rasi, bha) into
 which any circle is divided, and it is left to be determined

¹ Synonym for रेवती—"चन्ते रेवती पौष्ण पूष्ण इति च कथ्यते ।"

by the connection, in any case, from what point they shall be counted."—Burgess, Translation of the S.S., page 181. Still more I should ask learned men to think over the meaning of Revati from *रेव-प्रवगतौ प्रवगतिः प्रुतगतिः*—Siddhanta Kaumudi (motion in very long interval of time): "एकमासो भवेद्वर्षो विमासो दीर्घ उच्यते । विमासस्तु प्रुतोन्नेयो....."—याज्ञवल्कर गिष्ठा । (मास—interval), and the design in the naming of the star will be evident to all.

Here I acknowledge my indebtedness to Prof. C. V. Raman, M.A., and Prof. N. K. Mazumdar, M.A., in kindly helping me with valuable books necessary in completing this paper.

In conclusion I express my heartfelt gratitude to the Hon'ble Sir Asutosh Mookerji, Kt., C.S.I., for his keen interest and never failing encouragement and allowing these papers to find a place in the Journal of the Department of Letters, Calcutta University.
